                               :230
                                             NA's
                                                    :230
```

Quite a few NA's.

Numerical Columns: 1 within quakers, and 230 in Altitude low/high/mean.

Next, nee to check what is happening in the rest of the data set, the character type.

Count of NA's per coloumn

```
#type of data, col = 2, type of function applied
apply(X=is.na(coffee_ratings), MARGIN = 2, FUN = sum)
```

There a quite a few missing values and many columns have many. I will be just removing some of the columns with too many missing values, for instance lot_number and farm_name. Additionally, I there will be removal of columns that do not heavily influence the goals of this project.

```

The parameters for defects, quakers, and average altitude seem to have quite a range for values. Additionally, it can be seen for these fields that the max points are quite a ways away from the mean.

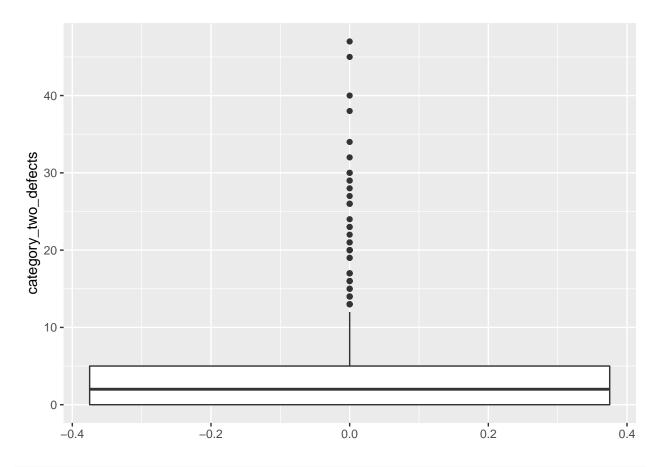

EDA / Visuals

library(ggplot2)

 $\# \mbox{Check}$ for outliers in some of the fields

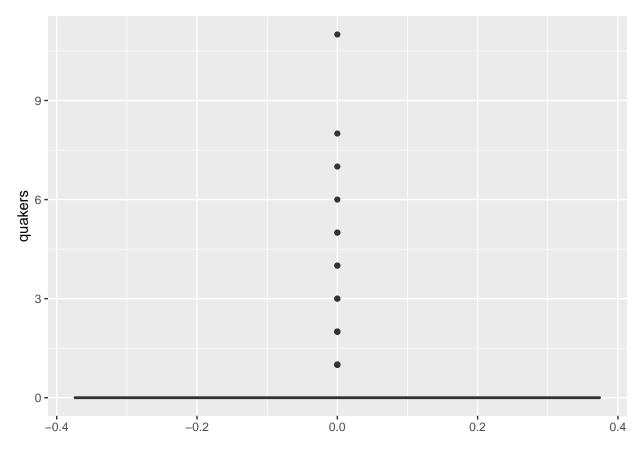

defect2_plt

alt_plt

quakers

There are some outliers, but not that many that would result in a concern at this time. These fields may be removed from the current analysis due to the outliers and lack of variance within the data. As the majority of these values are 0. This will be removed in the upcoming data chunks. Additionally, as this project is to have more focus in analysis, there will be additional removal of fields. Specifically, the ownership items and their location details.

#Redfine the Dataset

```
c = coffee[,c(1:2,4,10:26,28)]
```

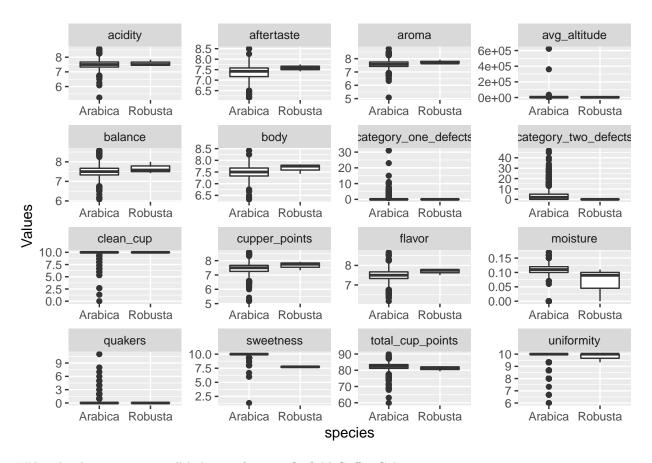

#Condense the data

```
c.v1 = c%>%pivot_longer(
  cols = !c(species, country_of_origin,variety,processing_method,color),
  names_to = "Variables",
  values_to = "Values")
```

Since, this data set will be re-used for other visuals. Otherwise the following code chunk could be used to generate a specific visual.

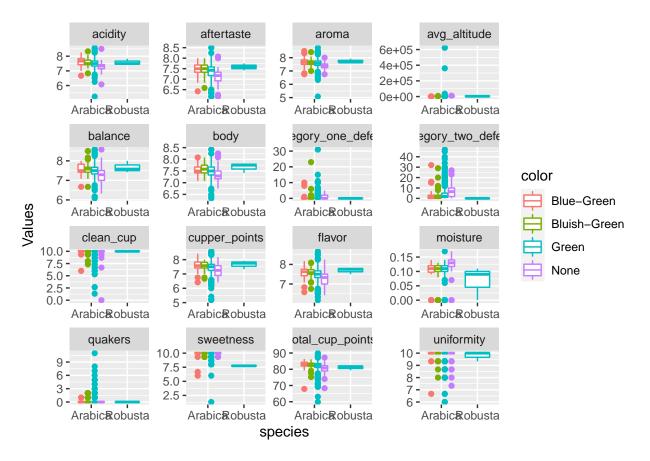

#Plot the data to see overall behavior

```
ggplot(c.v1,aes(x=species,y=Values))+geom_boxplot()+facet_wrap(~Variables,scales = "free")
```

##Analysis Preparation
#Format new label (total_cup_points) to be categorical
coffee$tcp = coffee$total_cup_points
#Creating Bins for the Cup Points
for(i in 1:894){
 if(coffee[i,29] >= 80){
    coffee[i,29] = 80
 else if(coffee[i,29] >= 70 \& coffee[i,29] < 80){
   coffee[i,29] = 70
```

```
}
else if(coffee[i,29] >= 60 & coffee[i,29] < 70){
   coffee[i,29] = 60
}
else{
   coffee[i,29] = 50
}
coffee$tcp = round(coffee$tcp,0)</pre>
```

While the bins could be more specific and look at every 2 or 5 points, it made more sense to use broader bins. This is due to trying to understand what makes a coffee from a specific bean have higher or lower overall cup points (i.e., what is the difference between 70s and 80s cup of coffee).

#Accuracy table for comparison between models

```
table_accuracy = matrix(nrow=4,ncol=1)
colnames(table_accuracy) = c('Accuracy')
rownames(table_accuracy) = c('DTree','NB','ANN','KNN')
table_accuracy
```

```
## Accuracy
## DTree NA
## NB NA
## ANN NA
## KNN NA
```

This is to help determining which model or models is better than the others. If there are many with similar accuracy, then the model that is the easiest to interpret and explain to a general audience.

#Set seed so analysis is repeatable

```
set.seed(1)
```

For analysis

```
df = coffee[,c(9:22,25,29)]
for(i in 4 : 13){
  df[,i]=round(df[,i],2)
}
```

If the data was processing a bit slowly for initial predicting, as it was too granular so this step was helpful to making the ML run quicker.

Fix issue with the Data#

```
df$processing_method= as.factor(df$processing_method)
df$variety = as.factor(df$variety)
df = df[,c(1:16)]
df$tcp = as.factor(df$tcp)
df$moisture = round(df$moisture,1)
```

This was missed earlier in the summary, but the fields that are characters, need to be changed to type factor for the analysis.

Simple k-fold cross validation(cv)

```
set.seed(1)
n = nrow(df)
folds = 10
tail = n%/%folds

rnd = runif(n)
rank = rank(rnd)

#block/chunk from cv
blk = (rank-1)%/%tail+1
blk = as.factor(blk)

#to see formation of folds
print(summary(blk))
```

```
## 1 2 3 4 5 6 7 8 9 10 11
## 89 89 89 89 89 89 89 89 89 89 4
```

Could turn the above into a more personalized cross validation method than one of the packages in an R library.

Predicitve Analysis

 $\# {\rm Decision} \ {\rm Tree}$

```
library(rpart)
set.seed(1)

all.acc = numeric(0)
for(i in 1:folds){
   tree = rpart(tcp~.,df[blk != i,],method="class")
   pred = predict(tree,df[blk==i,],type="class")
   confMat = table(pred,df$tcp[blk==i])
   acc = (confMat[1,1]+confMat[2,2]+confMat[3,3]+confMat[4,4])/sum(confMat)
   all.acc = rbind(all.acc,acc)
}

print(mean(all.acc))
```

```
## [1] 0.9516854
```

```
table_accuracy[1,1] = mean(all.acc)
```

A 95% overall accuracy is really good! This indicates if following this tree, with details on a bean one could reasonable figure out what its overall score will be prior to evaluation. It also indicates what are the more important parameters are for a coffee scoring.

Example of a table matrix of predicted(rows) and actual(columns)

pred 50 60 70 80 ## 50 0 0 0 0 ## 60 0 0 0 0

0 13

0

3 73

##

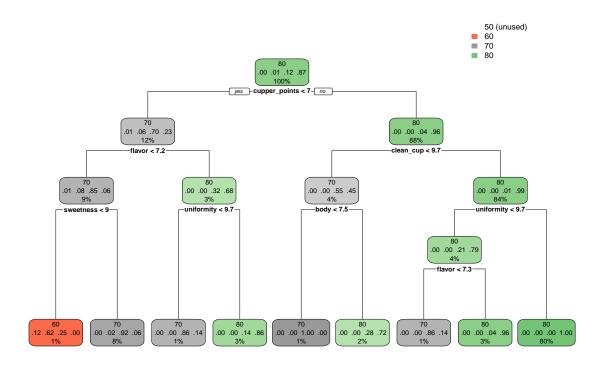

70 0

80 0 0

This indicates, for the given run, there were 3 miss classifications. Where the tree suggested that the bean should have been in the 80s, but was actually in the 70s.

Visual of Decision Tree

```
rpart.plot::rpart.plot(tree)
```

From this plot, I could just bin 50s with the 60sw group. This will help with future evaluations where re-binning the classifier would be a potential option to get more granular information.

Naive Bayes

```
library(e1071)

## Warning: package 'e1071' was built under R version 4.1.3

set.seed(1)

all.acc = numeric(0)
for(i in 1:folds){
   model = naiveBayes(tcp~.,df[blk != i,],method="class")
   pred = predict(model,df[blk==i,],type="class")
   confMat = table(pred,df$tcp[blk==i])
   acc = (confMat[1,1]+confMat[2,2]+confMat[3,3]+confMat[4,4])/sum(confMat)
   all.acc = rbind(all.acc,acc)
}

print(mean(all.acc))

## [1] 0.9550562

table_accuracy[2,1] = mean(all.acc)
```

Another nice and high accuracy for this PA!

Wierd R Issue

```
#switch the classifier to numerical
df$tcp = round(as.numeric(df$tcp),0)
#them switch it back to a factor
df$tcp = as.factor(df$tcp)
```

This was a very weird issue. I knew that this was a factor was needed for the classifier. However, it was throwing a NaN for an accuracy value and just by switching the format back and forth corrected it.

Neural Network

```
library(nnet)
set.seed(1)

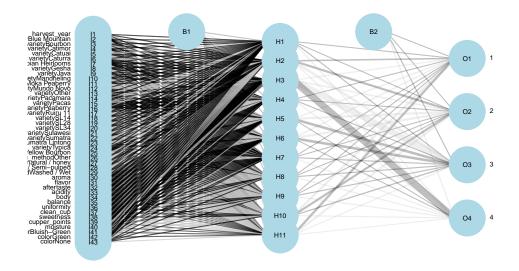

all.acc = numeric(0)
for(i in 1:folds){
  model = nnet(tcp~.,df[blk != i,], size = 11, trace=FALSE, rang=.06, decay=.006,maxit=500)
  pred = predict(model, df[blk=i,],type="class")
  confMat = table(factor(pred,levels=1:4),factor(df$tcp[blk=i],levels=1:4))
  acc = (confMat[1,1]+confMat[2,2]+confMat[3,3]+confMat[4,4])/sum(confMat)
  all.acc = rbind(all.acc,acc)
}
print(mean(all.acc))
```

```
table_accuracy[3,1] = mean(all.acc)
```

Not the best not the worst NN that I have seen. If there was more time, I would have liked to increased the classifiers and used a different library that allowed for more hidden layers.

Neuarl Network Visual

```
library("NeuralNetTools")
plotnet(model,circle_cex=5,cex_val=.4,max_sp=TRUE,alpha_val=.25,skip=TRUE)
```

Note

An issue I ran in to:

I re-formatted the label/target field and went from a binary (good [>74]/bad[<75]) classifier to what is it currently; 50s,60s,70s, and 80s. However, when running running the all of the PAs prior to neural network there were no strange issues. When running the NN I recieved an output accuracy of 0.003 an knew there was an issue.

There was an (un)interesting issue with NN table (well, all tables), as it was dropping the first two rows as it was not forward feeding into those nodes. The following is the work around to resolve this issue.

#Before

```
set.seed(1)
i=1
 model = nnet(tcp~.,df[blk != i,], size = 10, trace=FALSE, wgts=.05)
 pred = predict(model, df[blk==i,],type="class")
 confMat = table(pred,df$tcp[blk==i])
 confMat
##
## pred 1 2 3 4
     3 1 0 16 72
#After
set.seed(1)
i=1
 model = nnet(tcp~.,df[blk != i,], size = 10, trace=FALSE, wgts=.05)
 pred = predict(model, df[blk==i,],type="class")
 confMat = table(factor(pred,levels=1:4),factor(df$tcp[blk==i],levels=1:4))
 confMat
##
       1 2 3 4
##
##
    1
       0 0 0 0
##
    2 0 0 0 0
##
    3 1 0 16 72
    4 0 0 0 0
##
```

This was then applied to all of the PAs.

K-Nearest Neighbor Preparation

```
set.seed(1)
df$tcp = as.factor(df$tcp)
library (caret)

## Warning: package 'caret' was built under R version 4.1.3

## Loading required package: lattice

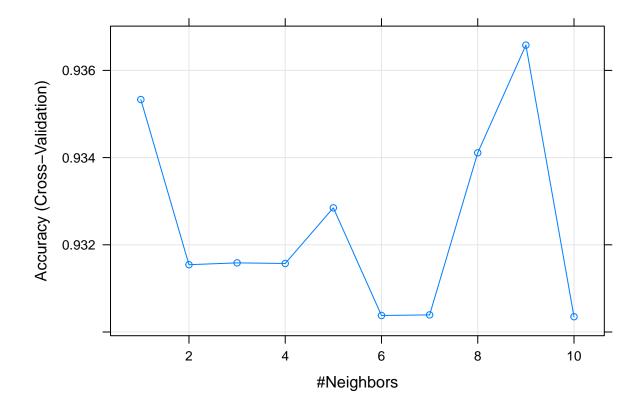

##
## Attaching package: 'caret'

## The following object is masked from 'package:purrr':

##
## lift
```

```
trControl <- trainControl(method = "cv", number = 10)
knn = df[,]</pre>
```

KNN

This is a visual to see how many neighbors the KNN will be running. From this visual it could possibly run at 9 groups due to the accuracy level.

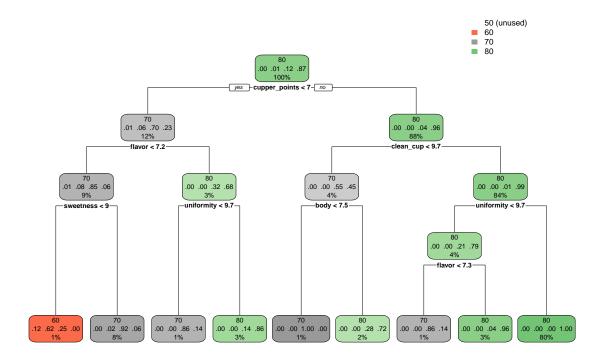

#View Accuracy Table

```
tab = round(table_accuracy,4)
tab
```

```
## Accuracy
## DTree 0.9517
## NB 0.9551
## ANN 0.8933
## KNN 0.9325
```

##Preferred Model

```
rpart.plot::rpart.plot(tree)
```

Top 3 parameters for understanding a coffee's score.

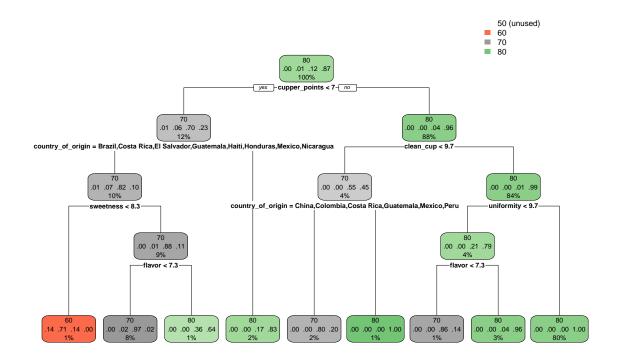

- ~Cupper points are the most informative parameter in deciding if a coffee is to be in the 80s or below this.
- ~If place coffee is <7 cupper points, the next deciding factor is how good is the flavor of the coffee.
- ~ If coffee is >7 cupper points, the next deciding factor is how clean the coffee leaves the cup.

For further analysis

```
df2 = coffee[,c(4,5,9:22,25,29)]
for(i in 6 : 16){
    df2[,i]=round(df2[,i],2)

df2$processing_method= as.factor(df2$processing_method)
df2$variety = as.factor(df2$variety)
df2$tcp = as.factor(df2$tcp)
df2$moisture = round(df2$moisture,1)
```

```
df2$color = as.factor(df2$color)
df2$country_of_origin = as.factor(df2$country_of_origin)
df2$region = as.factor(df2$region)
df3 = df2[,c(1,3:18)]
}
set.seed(1)
n = nrow(df3)
folds = 10
tail = n%/%folds
rnd = runif(n)
rank = rank(rnd)
#block/chunk from cv
blk = (rank-1)\%/\%tail+1
blk = as.factor(blk)
\#to see formation of folds
print(summary(blk))
## 1 2 3 4 5 6 7 8 9 10 11
## 89 89 89 89 89 89 89 89 89 4
set.seed(1)
all.acc = numeric(0)
for(i in 1:folds){
  tree = rpart(tcp~.,df3[blk != i,],method="class")
  pred = predict(tree,df3[blk==i,],type="class")
  confMat = table(pred,df3$tcp[blk==i])
 acc = (confMat[1,1]+confMat[2,2]+confMat[3,3]+confMat[4,4])/sum(confMat)
  all.acc = rbind(all.acc,acc)
print(mean(all.acc))
## [1] 0.947191
Interestingly, adding countries lowers the accuracy.
rpart.plot::rpart.plot(tree)
```

From the visual, it appears that Central and South America do not produce good coffee.
